

L'ecografia polmonare: quali informazioni aggiuntive rispetto alla radiografia del torace. Vogliamo convincere i cardio|logi che il polmone non è un buco nero degli ultrasuoni ma fonte di importanti elementi di diagnosi differenziale.

Un esame relativamente semplice ma che non si può improvvisare. Le informazioni utili nella diagnosi di edema polmonare, embolia polmonare, pneumotorace, versamento pleurico.

La diagnosi di ate|lettasia, edema interstiziale, paralisi del diaframma, polmonite, ARDS...

Abstract

Objectives To determine whether parachutes are effective in preventing major trauma related to gravitational challenge.

Design Systematic review of randomised controlled trials.

Data sources: Medline, Web of Science, Embase, and the Cochrane Library databases; appropriate internet sites and citation lists.

Study selection: Studies showing the effects of using a parachute during free fall.

Main outcome measure Death or major trauma, defined as an injury severity score >15.

Results We were unable to identify any randomised controlled trials of parachute intervention.

Conclusions As with many interventions intended to prevent ill health, the effectiveness of parachutes has not been subjected to rigorous evaluation by using randomised controlled trials. Advocates of evidence based medicine have criticised the adoption of interventions evaluated by using only observational data. We think that everyone might benefit if the most radical protagonists of evidence based medicine organised and participated in a double blind, randomised, placebo controlled, crossover trial of the parachute.

accepted intervention was a fabric device, secured by strings to a harness worn by the participant and released (either automatically or manually) during free fall with the purpose of limiting the rate of descent. We excluded studies that had no control group.

Definition of outcomes

The major outcomes studied were death or major trauma, defined as an injury severity score greater than 15.⁶

Meta-analysis

Our statistical approach was to assess outcomes in parachute and control groups by odds ratios and quantified the precision of estimates by 95% confidence intervals. We chose the Mantel-Haenszel test to assess heterogeneity, and sensitivity and subgroup analyses and fixed effects weighted regression techniques to explore causes of heterogeneity. We selected a funnel plot to assess publication bias visually and Egger's and Begg's tests to test it quantitatively. Stata software, version 7.0, was the tool for all statistical analyses.

Results

Our search strategy did not find any randomised controlled trials of the parachute.

ALI/ARDS DIAGNOSIS

A three-criteria system including chest radiograph, oxygenation score, and exclusion of cardiogenic causes.

- Acute onset, bilateral infiltrates on chest radiography
- Pulmonary-artery wedge pressure of < 18 mm Hg or the absence of clinical evidence of left atrial hypertension
- Acute lung injury considered present if $\text{PaO}_2/\text{FiO}_2 \leq 300$ and the ARDS subset was defined with a more severe oxygenation deficit, $\text{PaO}_2/\text{FiO}_2 \leq 200$

Bernard GR, Artigas A, Brigham KL, Carlet J, Falke K, Hudson L, Lamy M, Legall JR, Morris A, Spragg R. The American European consensus conference on ARDS: definitions mechanisms, relevant outcomes and clinical trial coordination. *Am J Respir Crit Care Med* 1994;149:818–824.

Acute Respiratory Distress Syndrome

The Berlin Definition

JAMA. 2012;307(23):2526-2533

Published online May 21, 2012. doi:10.1001/jama.2012.5669

Table 3. The Berlin Definition of Acute Respiratory Distress Syndrome

Acute Respiratory Distress Syndrome	
Timing	Within 1 week of a known clinical insult or new or worsening respiratory symptoms
Chest imaging ^a	Bilateral opacities—not fully explained by effusions, lobar/lung collapse, or nodules
Origin of edema	Respiratory failure not fully explained by cardiac failure or fluid overload Need objective assessment (eg, echocardiography) to exclude hydrostatic edema if no risk factor present
Oxygenation ^b	
Mild	$200 \text{ mm Hg} < \text{PaO}_2/\text{FiO}_2 \leq 300 \text{ mm Hg}$ with PEEP or CPAP $\geq 5 \text{ cm H}_2\text{O}$ ^c
Moderate	$100 \text{ mm Hg} < \text{PaO}_2/\text{FiO}_2 \leq 200 \text{ mm Hg}$ with PEEP $\geq 5 \text{ cm H}_2\text{O}$
Severe	$\text{PaO}_2/\text{FiO}_2 \leq 100 \text{ mm Hg}$ with PEEP $\geq 5 \text{ cm H}_2\text{O}$

Abbreviations: CPAP, continuous positive airway pressure; FiO₂, fraction of inspired oxygen; PaO₂, partial pressure of arterial oxygen; PEEP, positive end-expiratory pressure.

^aChest radiograph or computed tomography scan.

^bIf altitude is higher than 1000 m, the correction factor should be calculated as follows: [$\text{PaO}_2/\text{FiO}_2 \times (\text{barometric pressure}/760)$].

^cThis may be delivered noninvasively in the mild acute respiratory distress syndrome group.

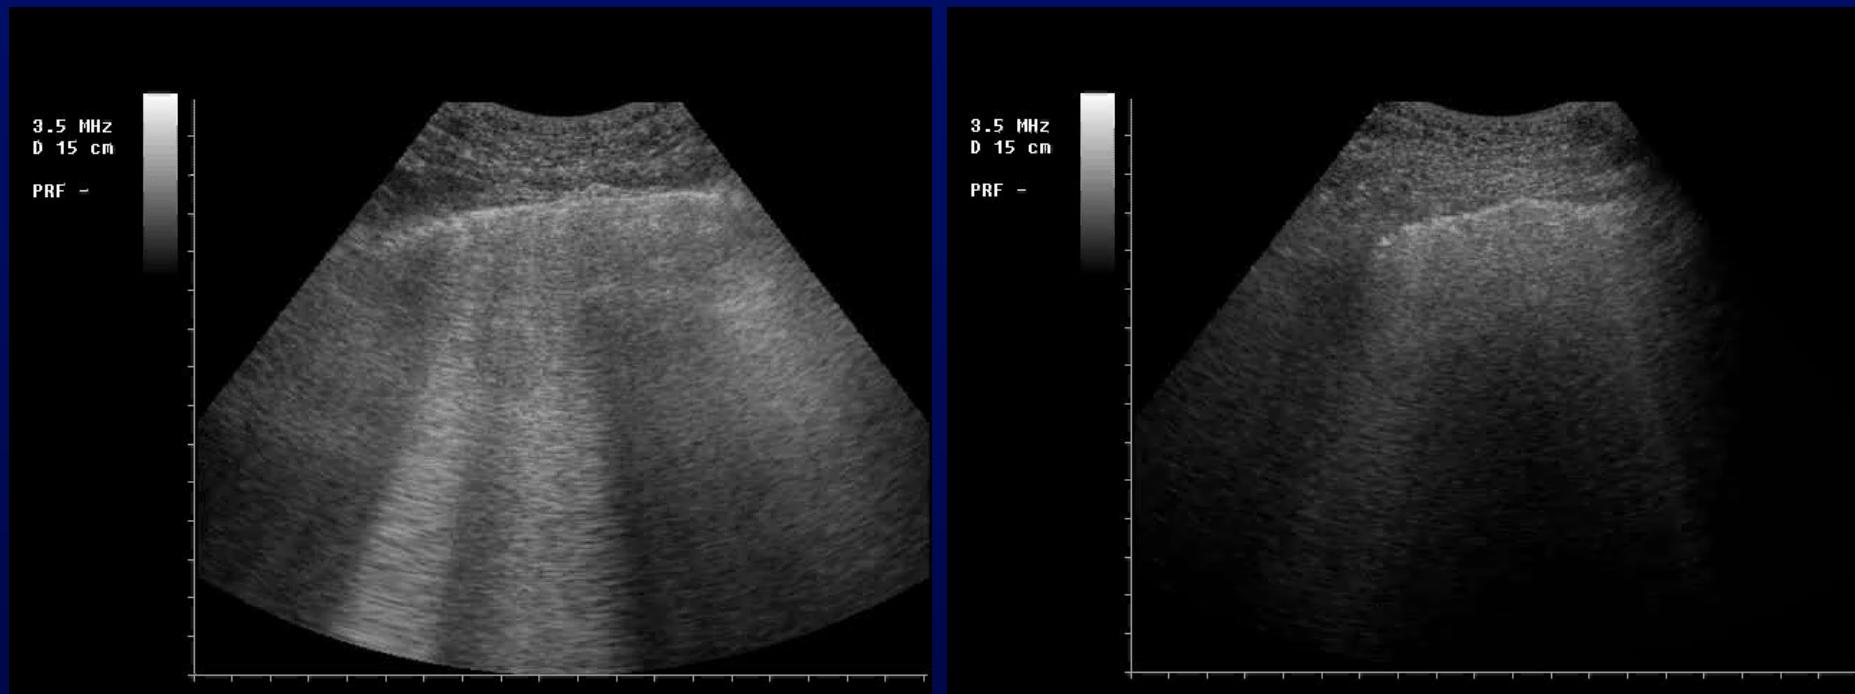

Radiographically, the findings are indistinguishable from those of cardiogenic pulmonary edema. Bilateral infiltrates may be patchy or asymmetric and may include pleural effusions.

- The CT has shown us that the lung was not uniformly involved. There are areas of the lung that are severely affected by an injury, areas that are mildly involved, and areas that are not involved at all.
- Alveolar filling, consolidation, and atelectasis occur predominantly in dependent lung zones, whereas other areas may be relatively spared.
- CT scan useful for to investigate the “potential for recruitment”
- CT scan useful in detecting complications (occult pneumothorax, pneumomediastinum, pneumatocele, septic emboli)

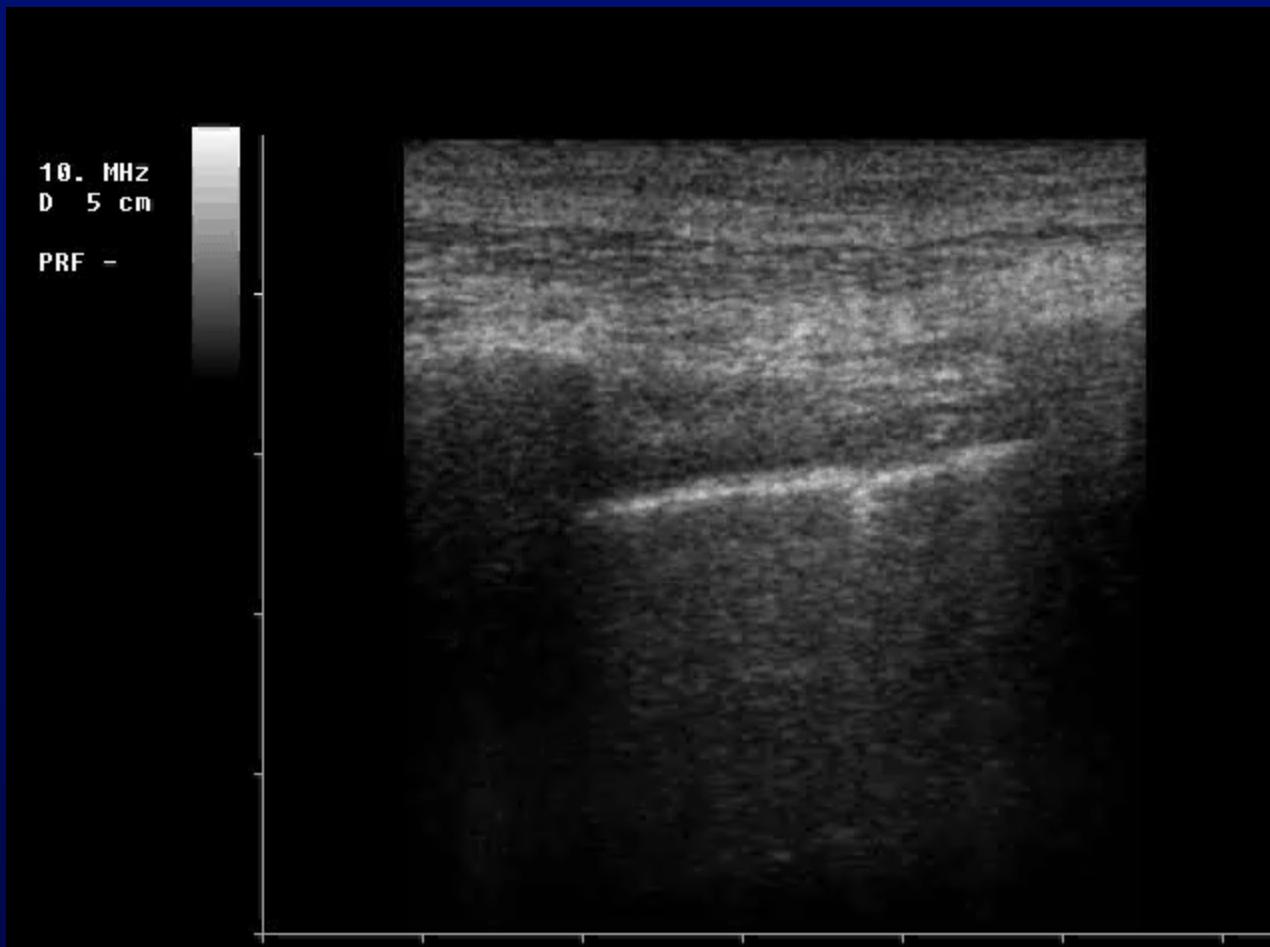

DISADVANTAGES OF CT SCAN

- **Costly resource of limited availability**
- **Exposes the patient to a high amount of radiation**
- **Exposes the patient to the risk of transfer to the CT suite**
- **CT specificity is not 100%**
