3. Definitions and classifications

The term PAH describes a group of PH patients characterized haemodynamically by the presence of pre-capillary PH, defined by a pulmonary artery wedge pressure (PAWP) ≤15 mmHg and a PVR >3 Wood units (WU) in the absence of other causes of pre-capillary PH such as PH due to lung diseases, CTEPH or other rare diseases.[1]

European Heart Journal 2016;37:67–119

Definition	Characteristics[a]	Clinical group(s)[b]
PH	PAPm ≥25 mmHg	All
Pre-capillary PH	PAPm ≥25 mmHg PAWP ≤15 mmHg	1. Pulmonary arterial hypertension 3. PH due to lung diseases 4. Chronic thromboembolic PH 5. PH with unclear and/or multifactorial mechanisms

RISK FACTORS AND ASSOCIATED CONDITIONS

Connective Tissue Disease
Congenital Heart Disease
Portal Hypertension
HIV Infection
Drugs and Toxins
Pregnancy

SUSCEPTIBILITY
Abnormal BMPR2 Gene
Other Genetic Factors

VASCULAR INJURY

Endothelial Dysfunction

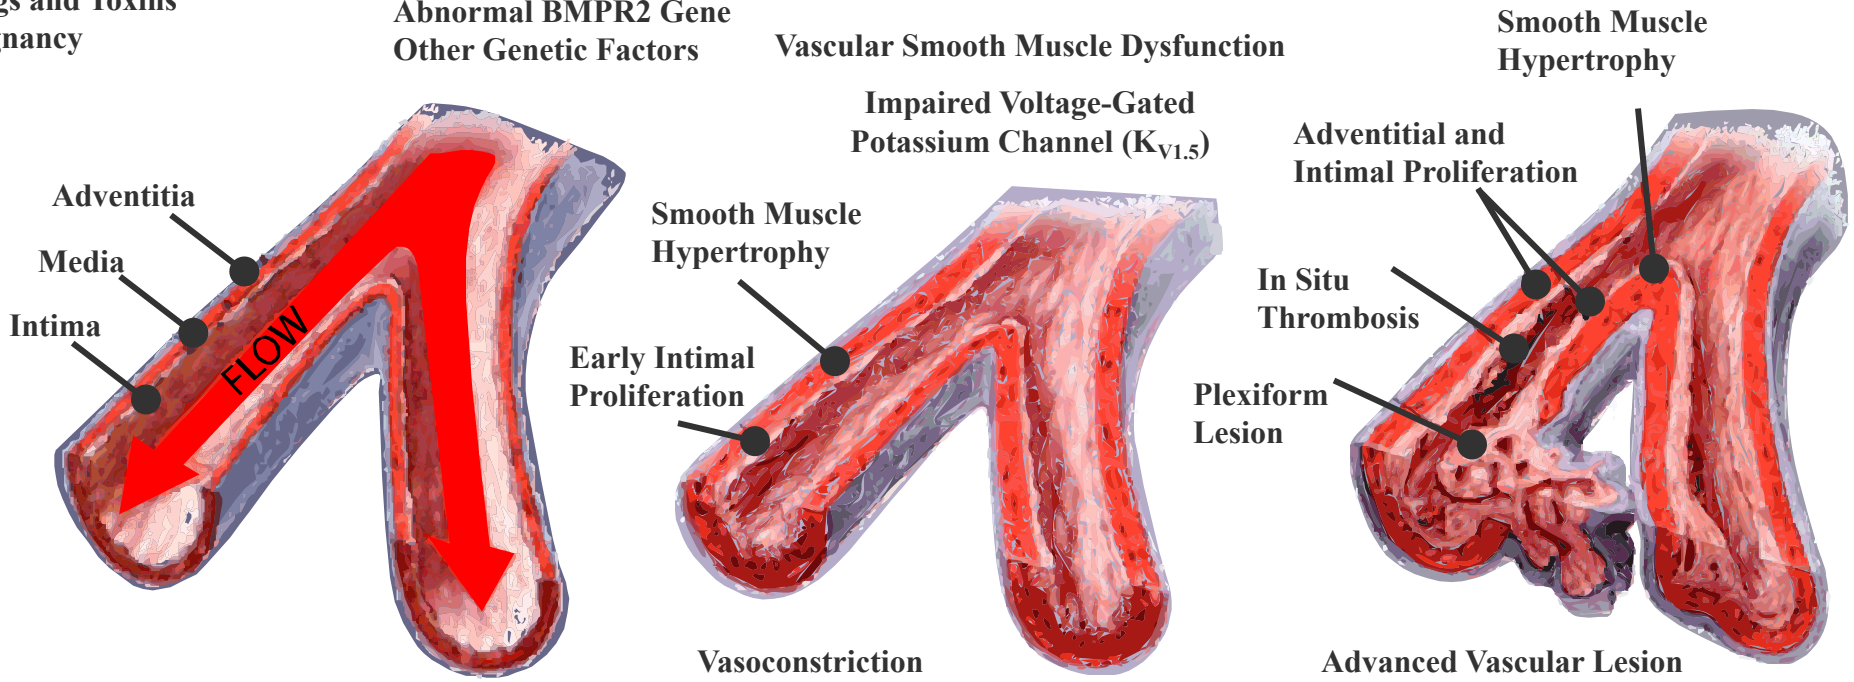
↓Nitric Oxide Synthase
↓Prostacyclin Production
↑Thromboxane Production
↑Endothelin 1 Production

Vascular Smooth Muscle Dysfunction

Impaired Voltage-Gated Potassium Channel ($K_{V1.5}$)

DISEASE PROGRESSION

Loss of Response to Short-Acting Vasodilator Trial



NORMAL — REVERSIBLE DISEASE — IRREVERSIBLE DISEASE

5. Pulmonary hypertension diagnosis

5.1 Diagnosis

The diagnosis of PH requires a clinical suspicion based on symptoms and physical examination

Peak tricuspid regurgitation velocity (m/s)	Presence of other echo 'PH signs'[a]	Echocardiographic probability of pulmonary hypertension
≤2.8 or not measurable	No	Low
≤2.8 or not measurable	Yes	Intermediate
2.9–3.4	No	
2.9–3.4	Yes	High
>3.4	Not required	

A: The ventricles[a]	B: Pulmonary artery[a]	C: Inferior vena cava and right atrium[a]
Right ventricle/ left ventricle basal diameter ratio >1.0	Right ventricular outflow Doppler acceleration time <105 msec and/or midsystolic notching	Inferior cava diameter >21 mm with decreased inspiratory collapse (<50 % with a sniff or <20 % with quiet inspiration)
Flattening of the interventricular septum (left ventricular eccentricity index >1.1 in systole and/or diastole)	Early diastolic pulmonary regurgitation velocity >2.2 m/sec	Right atrial area (end-systole) >18 cm^2
	PA diameter >25 mm.	

2015 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension

ESC/ERS GUIDELINES

EUROPEAN SOCIETY OF CARDIOLOGY®

5. Pulmonary hypertension diagnosis

5.1 Diagnosis

The diagnosis of PH requires a comprehensive set of investigations to confirm that haemodynamic criteria are met and to describe the aetiology and the functional and haemodynamic severity of the condition. The interpretation of these investigations requires, at the very least, expertise in cardiology, imaging and respiratory medicine and may best be discussed at a multidisciplinary team meeting.

European Heart Journal 2016;37:67–119

2015 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension

12. Definition of a pulmonary hypertension referral centre

- The importance of expert referral centres in the management of PH patients has been highlighted in both the diagnostic and treatment algorithms.

Recommendations	Class[a]	Level[b]
It is recommended for referral centres to provide care by a multiprofessional team (cardiology and respiratory medicine physicians, clinical nurse specialist, radiologists, psychological and social work support, appropriate on-call expertise)	I	C
It is recommended for referral centres to have direct links and quick referral patterns to other services (such as CTD, family planning, PEA, lung transplantation, adult congenital heart disease)	I	C
It should be considered that a referral centre follow at least 50 patients with PAH or CTEPH and should receive at least two new referrals per month with documented PAH or CTEPH	IIa	C
It should be considered that a referral centre perform at least 20 vasoreactivity tests in IPAH, HPAH or DPAH patients per year	IIa	C
Referral centres should participate in collaborative clinical research in PAH, including phase II and phase III clinical trials	IIa	C

4. Epidemiology and genetics of pulmonary hypertension

5.1.12 Genetic testing

Genetic counselling and *BMPR2* mutation screening (point mutations and large rearrangements) should be offered by referral centres to patients with IPAH considered to be sporadic or induced by anorexigens and to patients with a family history of PAH.

European Heart Journal 2016;37:67–119

2015 ESC/ERS Guidelines for the diagnosis and treatment of pulmonary hypertension

ESC/ERS GUIDELINES

EUROPEAN SOCIETY OF CARDIOLOGY

4.2 Genetics

- Group 1 (PAH): Heterozygous *BMPR2* mutations account for approximately 75% of familial PAH and up to 25% of apparently sporadic PAH cases.[26] *BMPR2* encodes a type 2 receptor for bone morphogenetic proteins involved in the control of vascular cell proliferation.

When no *BMPR2* mutations are identified in familial PAH patients or in IPAH patients <40 years old, or when PAH occurs in patients with a personal or familial history of hereditary haemorrhagic telangiectasia, screening of the *ACVRL1* and *ENG* genes may be performed. If no mutations in the *BMPR2*, *ACVRL1* and *ENG* genes are identified, screening of rare mutations may be considered (*KCNK3*, *CAV1*, etc.).

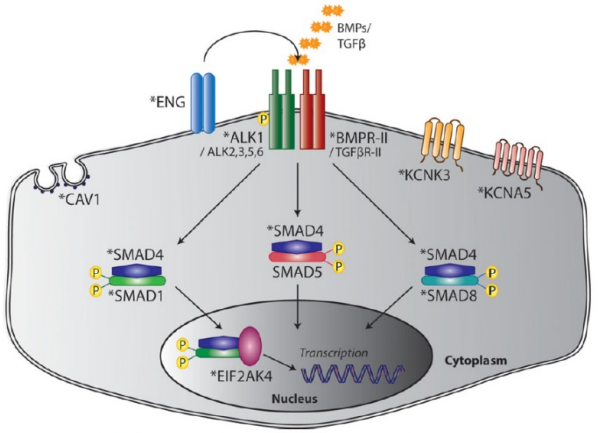

Figure 1. Schematic of canonical BMP signaling and additional pathways implicated in PAH pathogenesis by conventional and next-generation sequence analysis. Causal genes are indicated by the asterisks.

Early detection and management of pulmonary arterial hypertension

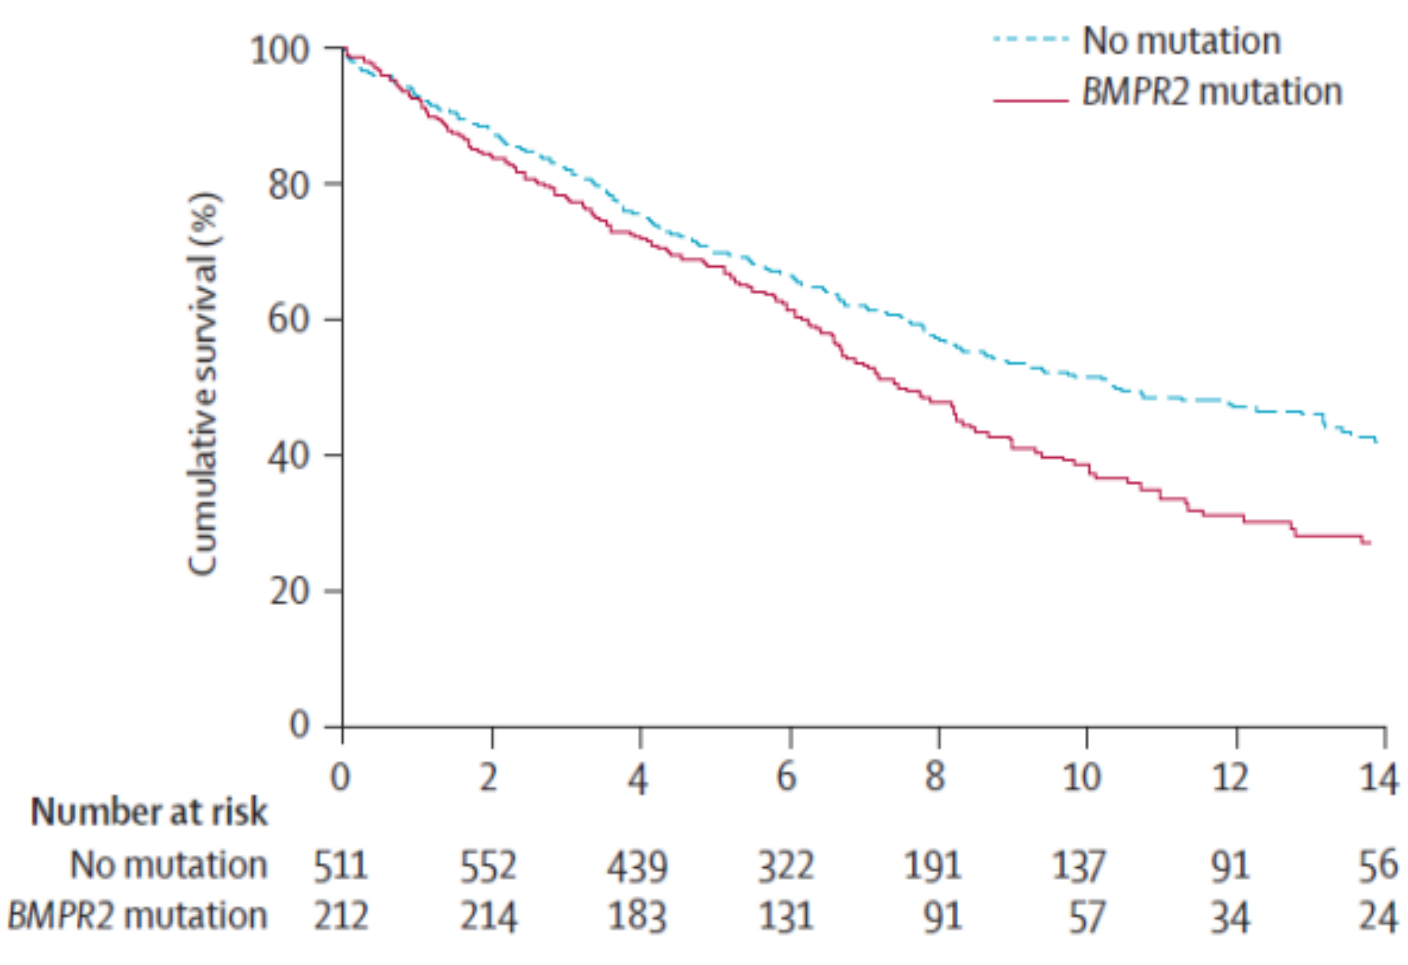
Marc Humbert*, J. Gerry Coghlan# and Dinesh Khanna¶

Screening is defined as the systematic testing of asymptomatic individuals for pre-clinical disease

Web Table X Recommendations for pulmonary arterial hypertension screening

Recommendations	Class [a]	Level [b]
Resting echocardiography is recommended as a screening test in asymptomatic patients with systemic sclerosis.	I	B
Resting echocardiography is recommended as a screening test in *BMPR2* mutation carriers or first-degree relatives of patients with HPAH and in patients with PoPH referred for liver transplantation.	I	C
A combined approach (including biomarkers, PFTs and echocardiography) should be considered to predict PH in systemic sclerosis.	IIa	B
Systemic sclerosis patients with a mean PAP ranging from 21 to 24 mmHg should be closely monitored, because of a higher risk of PAH.	IIa	B
Initial screening using the stepwise DETECT algorithm may be considered in adult systemic sclerosis patients with >3 years' disease duration and a DLCO <60% predicted.	IIb	B
Annual screening with echocardiography, PFTs and biomarkers may be considered in patients with systemic sclerosis.	IIb	B
In individuals who test positive for PAH-causing mutations and first-degree relatives of HPAH cases may be considered to have an annual screening echocardiogram.	IIb	C
Exercise echocardiography is not recommended to predict PH in high risk population.	III	C

BMPR2 mutations and survival in pulmonary arterial hypertension: an individual participant data meta-analysis



Implications of all the available evidence

Patients with PAH with underlying *BMPR2* mutations are younger at diagnosis, have more severe disease, and have a worse prognosis than patients without *BMPR2* mutations.

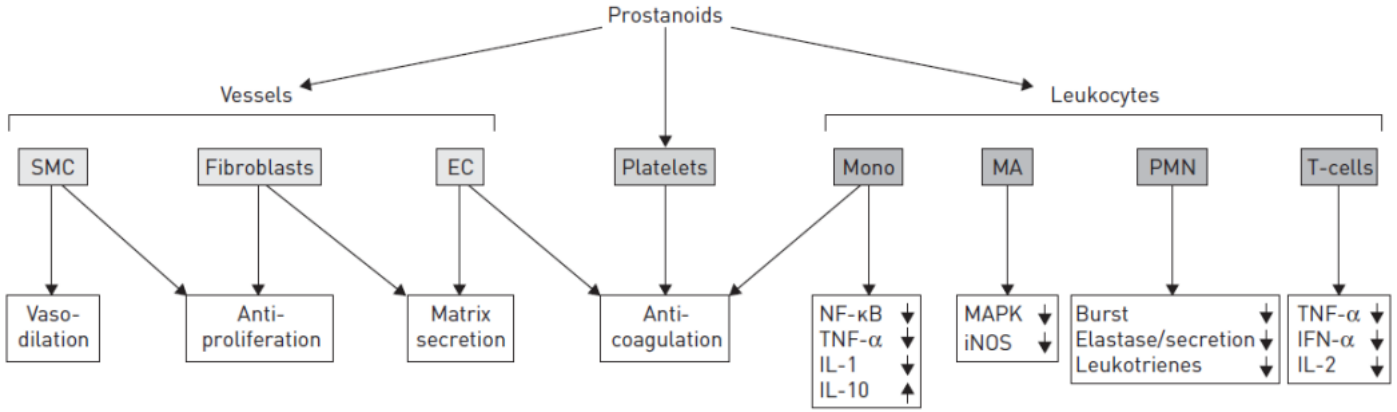
Epoprostenol and pulmonary arterial hypertension: 20 years of clinical experience

REVIEW
PULMONARY ARTERIAL HYPERTENSION

Olivier Sitbon[1,2,3] and Anton Vonk Noordegraaf[4]



Conclusion

Epoprostenol has been an important treatment for PAH for two decades and its place in patient management continues to evolve. As the first disease-specific treatment for PAH, and the first therapy shown in an RCT to improve patient survival, epoprostenol transformed PAH management and opened the door to a new era of scientific and clinical study of PAH. With a wealth of clinical data supporting the efficacy and tolerability profile of epoprostenol, this agent remains a key treatment option in PAH, and the development of new, more convenient formulations of this therapy looks set to ensure a continuing role for epoprostenol within the management of patients with PAH.

Eur Respir Rev 2017; 26: 160055

Upfront triple combination therapy in pulmonary arterial hypertension: a pilot study

Olivier Sitbon[1,2,3], Xavier Jaïs[1,2,3], Laurent Savale[1,2,3], Vincent Cottin[4], Emmanuel Bergot[5], Elise Artaud Macari[1,2,3], Hélène Bouvaist[6], Claire Dauphin[7], François Picard[8], Sophie Bulifon[1,2,3], David Montani[1,2,3], Marc Humbert[1,2,3] and Gérald Simonneau[1,2,3]

ABSTRACT Patients with severe pulmonary arterial hypertension (PAH) in New York Heart Association (NYHA) functional class (FC) III/IV have a poor prognosis, despite survival benefits being demonstrated with intravenous epoprostenol. In this pilot study, the efficacy and safety of a triple combination therapy regimen in patients with severe PAH was investigated.

Data from newly diagnosed NYHA FC III/IV PAH patients (n=19) initiated on upfront triple combination therapy (intravenous epoprostenol, bosentan and sildenafil) were collected retrospectively from a prospective registry.

Survival analysis

All patients initiated with upfront triple combination therapy were still alive after a mean follow up of 41.2±13.4 months. Overall survival estimates were 100%, 100% and 100% at 1, 2 and 3 years, and respective transplant-free survival estimates were 94%, 94% and 94%. Expected survival calculated from the French equation was 75% (95% CI 68–82%), 60% (95% CI 50–70%) and 49% (95% CI 38–60%) at 1, 2 and 3 years, respectively.

Most of the proposed variables and cut-off values are based on expert opinion

They may provide prognostic information and may be used to guide therapeutic decisions, but application to individual patients must be done carefully

One must also note that most of these variables have been validated mostly for IPAH and the cut-off levels used above may not necessarily apply to other forms of PAH

Furthermore, the use of approved therapies and their influence on the variables should be considered in the evaluation of the risk

Evaluation of severity

The clinical assessment of the patient has a pivotal role in the choice of the initial treatment, the evaluation of the response to therapy, and the possible escalation of therapy if needed.

6.2.4 Comprehensive prognostic evaluation and risk assessment

Regular assessment of patients with PAH in expert PH centres is strongly recommended.

III. The Left and Right Atria

GUIDELINES AND STANDARDS

Recommendations for Cardiac Chamber Quantification by Echocardiography in Adults: An Update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging

III. THE LEFT AND RIGHT ATRIA

J Am Soc Echocardiogr 2015;28:1–39

10. Right Atrial measurements

As with the left atrium, RA volumes are likely to be more robust and accurate for determination of RA size compared with linear dimensions.

Recommendations. The recommended parameter to assess RA size is RA volume, calculated using single-plane area-length or disk summation techniques in a dedicated apical four-chamber view.

Volume.
2D volumetric measurements are usually based on tracings of the blood-tissue interface on the apical four-chamber view. At the tricuspid valve level, the contour is closed by connecting the two opposite sections of the tricuspid ring with a straight line. Volumes can be computed by using either the single plane area-length:

$$\frac{8}{3\pi}\left[\frac{(A)^2}{L}\right]$$

or the disks summation technique. 3D data sets are usually obtained from the apical approach using a full-volume acquisition

2D view

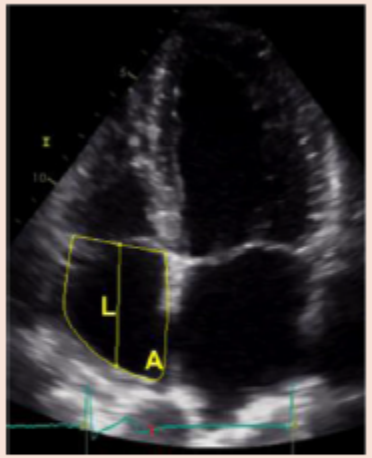

Table 13 Normal RA size obtained from 2D echocardiographic studies

	Women	Men
RA minor axis dimension (cm/m^2)	1.9 ± 0.3	1.9 ± 0.3
RA major axis dimension (cm/m^2)	2.5 ± 0.3	2.4 ± 0.3
2D echocardiographic RA volume (mL/m^2)	21 ± 6	25 ± 7

- More representative of actual RA size than linear dimensions

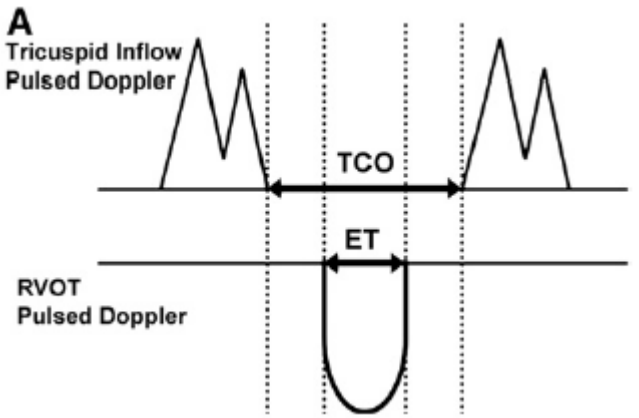
Recommendations for Cardiac Chamber Quantification by Echocardiography in Adults: An Update from the American Society of Echocardiography and the European Association of Cardiovascular Imaging



II. The Right Ventricle

8. RV Systolic Function

RV systolic function has been evaluated using multiple parameters (*Table 9*), including RIMP, TAPSE, 2D FAC, 3DEEF, S′, and longitudinal strain and strain rate by DTI and 2D STE.[25]

Recommendations

Two-dimensional STE-derived strain, particularly of the RV free wall, appears to be reproducible and feasible for clinical use. Because of the need for additional normative data from large studies involving multi-vendor equipment, no definite reference ranges are currently recommended for either global or regional RV strain or strain rate.

a marked increase (>30 mmHg) of PAPs during exercise reflects better RV function and is associated with a better long-term outcome than a modest or no increase.[111] This so-called contractile reserve has recently been shown to be an independent prognostic marker in patients with severe PH.[111]

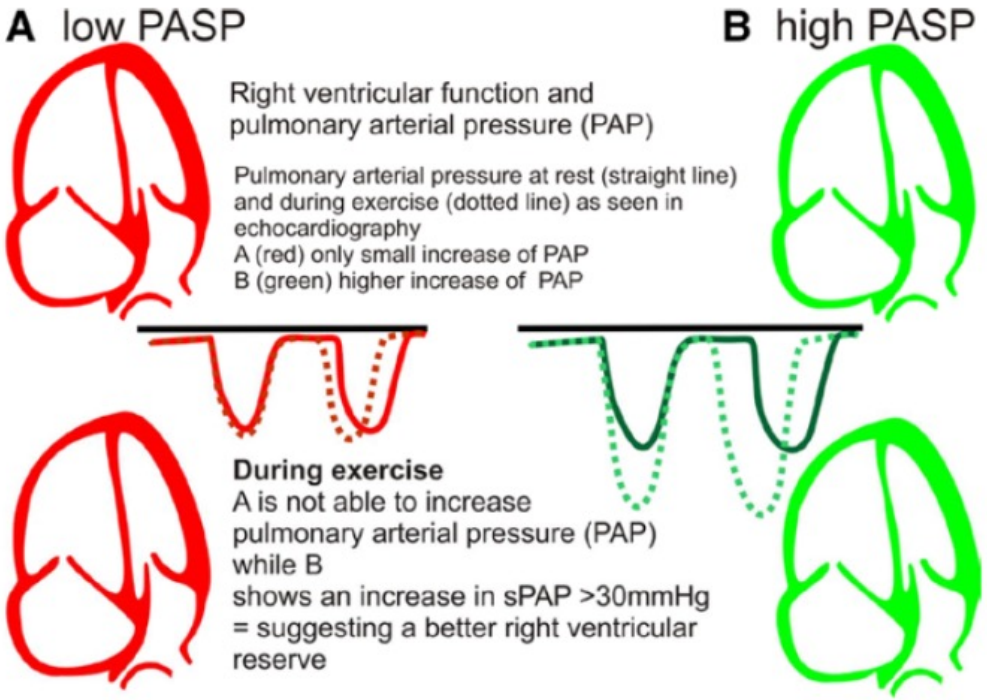
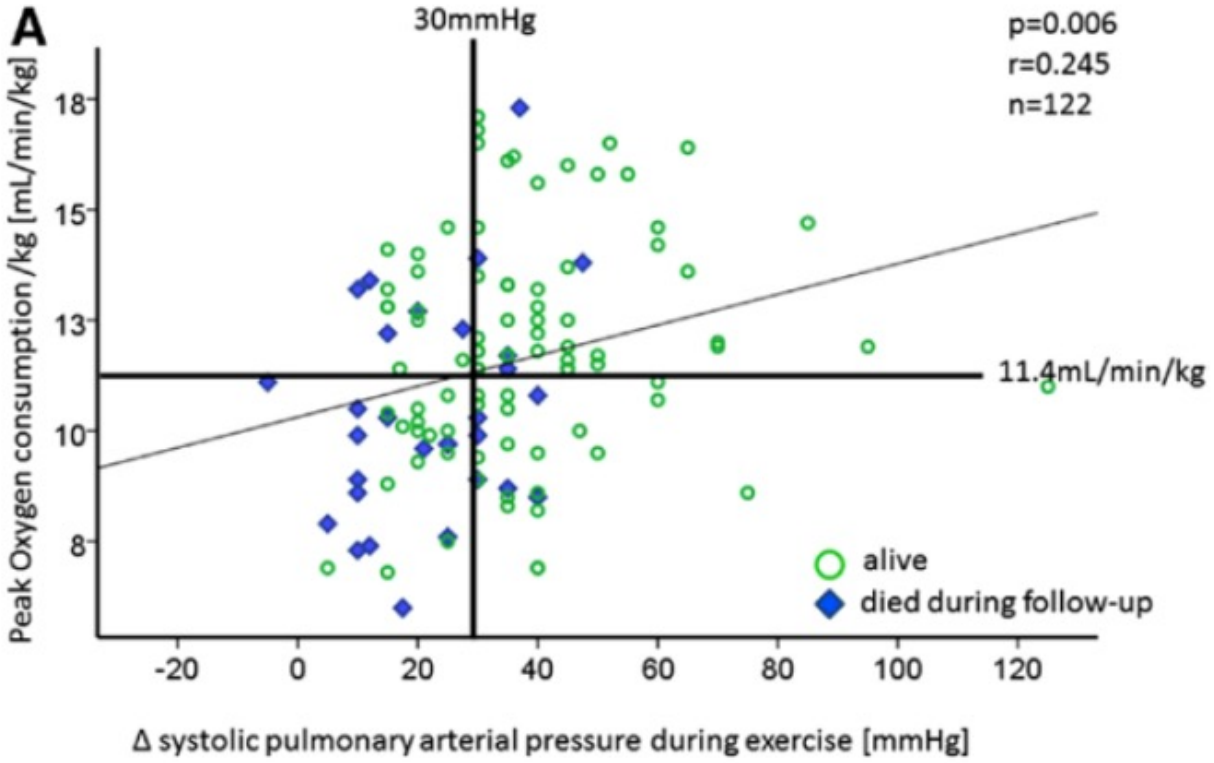
Circulation 2013;128:2005–2015

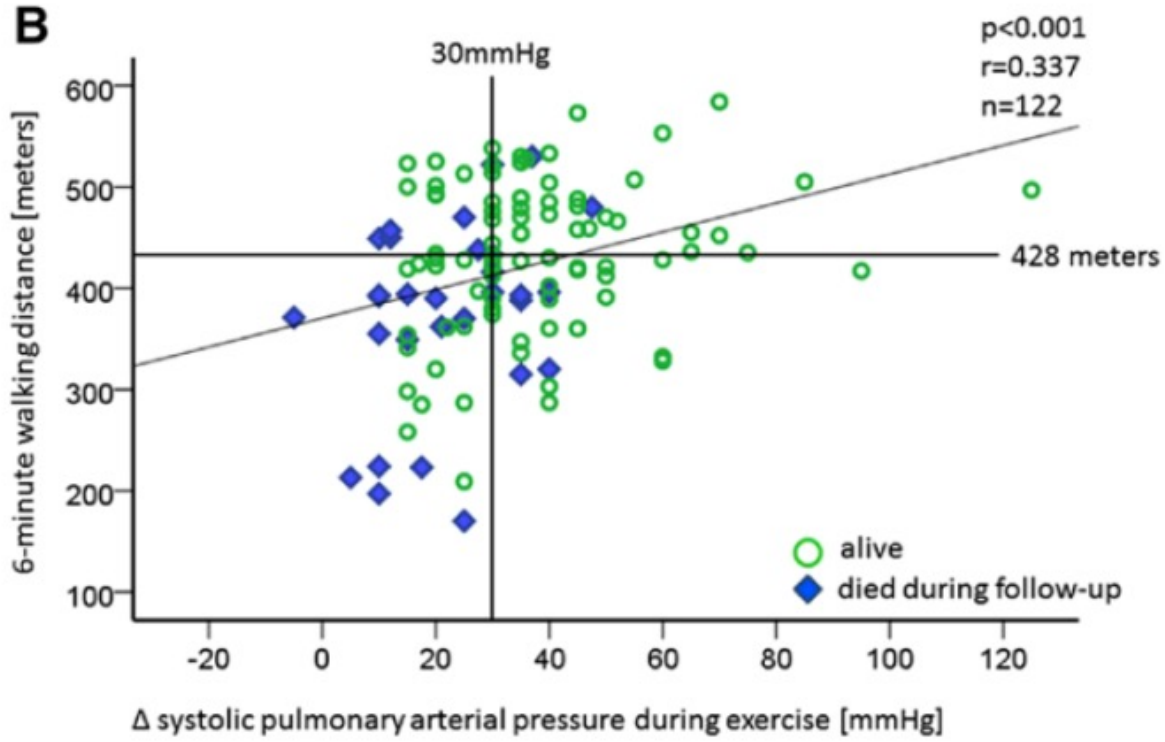
Clinical Implications and Conclusions

Assessment of PASP increase during exercise by stress echocardiography at low workloads may reflect RV contractile reserve and can contribute to follow-up assessment and risk stratification of PAH/CTEPH patients. The combination of stress Doppler echocardiography and cardiopulmonary exercise test revealed the most important independent prognostic factors to be peak $\dot{V}O_2$ and low PASP increase and may be useful for therapeutic decision making by identifying patients of especially high risk and inadequate therapy. Estimation of RV contractile reserve may be even more important than resting hemodynamics measured by echocardiography for the follow-up and therapeutic management of PH patients.



Assessment and Prognostic Relevance of Right Ventricular Contractile Reserve in Patients With Severe Pulmonary Hypertension





Circulation 2013;128:2005–2015

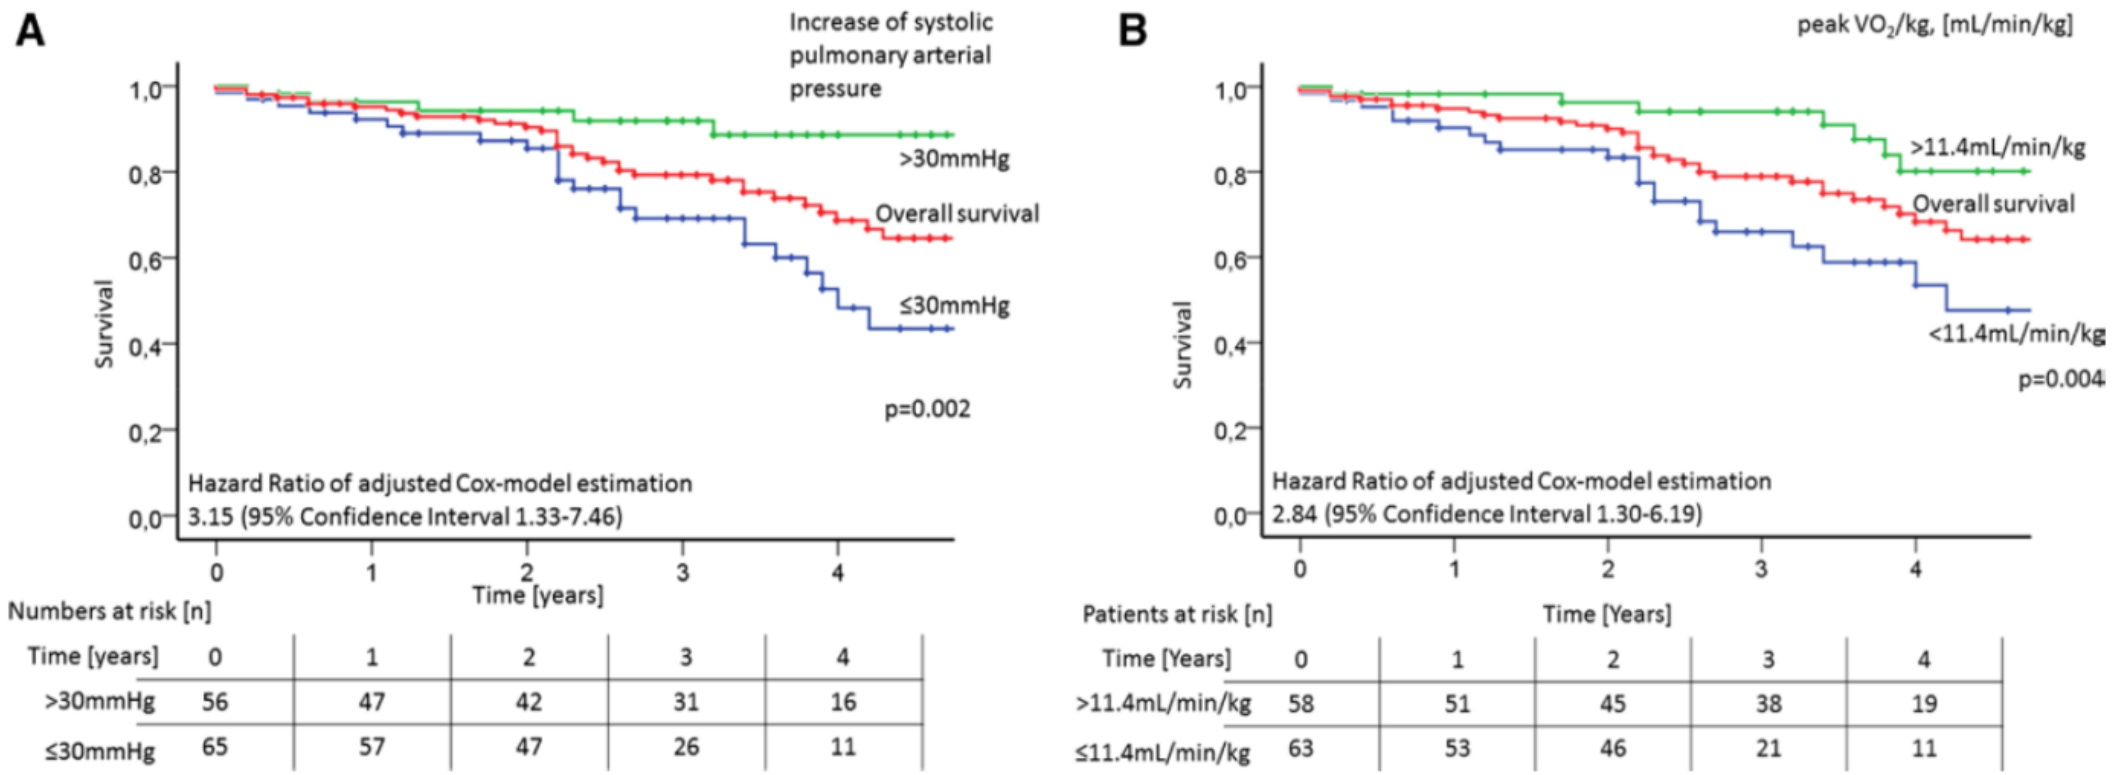


Figure 4. A, Survival rate of pulmonary hypertension patients in relation to right ventricular contractile reserve obtained by pulmonary arterial systolic pressure (PASP) increase during exercise. The 1-, 3-, and 4-year survival rates among the patients with PASP increase ≤30 mm Hg were 92%, 69%, and 48%, respectively, and 96%, 92%, and 89% among group B with high PASP >30 mm Hg. **B**, Survival among patients in relation to peak $\dot{V}O_2$ per kilogram. The median of peak $\dot{V}O_2$ per kilogram (11.4 mL·min^{-1}·kg^{-1}) was used to split the patients into 2 groups. Patients with a peak $\dot{V}O_2$ per kilogram >11.4 mL·min^{-1}·kg^{-1} had significantly higher survival rates (98%, 93%, and 80%) than patients with peak $\dot{V}O_2$ per kilogram ≤11.4 mL·min^{-1}·kg^{-1} (90%, 67% and 56%) at 1, 3, and 4 years.

Accuracy of Right Ventricular Volumes and Function Determined by Three-Dimensional Echocardiography in Comparison with Magnetic Resonance Imaging: A Meta-Analysis Study

Yuichi J. Shimada, MD, Maiko Shiota, MD, Robert J. Siegel, MD, and
Takahiro Shiota, MD, PhD, FACC, FASE, FAHA, *New York, New York; Los Angeles and Palo Alto, California*

CONCLUSIONS

Only by synthesizing a number of small studies in a meta-analysis could we display an underestimation of RV volumes and EF by 3DE and factors of the systematic bias. Furthermore, semiautomated tracking systems, matrix-array transducers, software for diseased right ventricles, spatial and temporal resolution, and time for obtaining images were identified as targets for development. These data provide a more detailed basis for analyzing and improving the accuracy of 3DE, an indispensable step toward further clinical application in RV assessment.
